

Report No. 475

Results of a Pilot Survey on Suitability of Different Reference Periods for Measuring Household Consumption

January – June 2000

**National Sample Survey Organisation
Ministry of Statistics & Programme Implementation
Government of India**

September 2002

Preface

In 1972 the National Sample Survey Organisation (NSSO) began a quinquennial series of all-India surveys on consumer expenditure, employment & unemployment. In addition to this, an annual series of consumer expenditure surveys was started in 1986. These annual surveys have been conducted on a smaller scale during NSS rounds intervening between the large scale quinquennial surveys, which had other subjects of enquiry as their focus. As a result, an annual series of data on consumer expenditure has since become available.

In the formative years of NSS surveys, considerable attention was paid to the length of reference period suitable for ascertaining the correct volume of consumption of different items of goods and services. Recently, a question arose as to whether a reference period of a week or a month was more suitable for collection of consumption data on items of food, pan, tobacco and intoxicants. Consequently, an Expert Group under the chairmanship of Prof Nihilesh Bhattacharya was formed by the Min. of Statistics and PI and a Pilot Survey was carried out during January to June 2000.

This report brings out the findings of the Pilot Survey on suitability of reference period for measuring household consumption. It appears that for both rural and urban areas, the 'last week' reference period would be more appropriate than the 'last month' reference period for many groups of items, e.g., vegetables, fresh fruits and spices, and for 'all food', as a whole, and for pan, tobacco and intoxicants. However, for some groups viz., cereals and products, liquid milk and sugar, 'last month' estimates look better or at least equally reasonable, and so 'last month' could be retained as reference period for such groups.

The fieldwork for the survey was handled by the Field Operations Division, the data was processed by the Data Processing Division, and the report was prepared by the Expert Group headed by Prof Bhattacharya in collaboration with the officers of the Survey Design and Research Division of the NSSO. I am grateful to the members of the Governing Council of NSSO, the members of the Expert Group, the Heads of various Divisions of the NSSO and their colleagues for their contributions at various stages. The report, I hope, will be useful in deciding a suitable reference period in the collection of data on items of food, pan, tobacco and intoxicants in future surveys of household consumption in India.

Comments/suggestions from readers will be most welcome.

Results of a Pilot Survey on Suitability of Different Reference Periods for Measuring Household Consumption *

1. Introduction and Background

Sample surveys on household consumption expenditure have been carried out in many rounds of the NSS ever since the inception of NSS in 1950, and much attention has been paid to the choice of appropriate reference periods for collecting household consumption expenditure data by the interview method. In the quinquennial surveys conducted during 1972-73 (27th round), 1977-78 (32nd round), 1983 (38th round), 1987-88 (43rd round) and 1993-94 (50th round), the reference period used was 'last month' or 'last 30 days' for all items of the budget; but 'last 365 days' was also used in addition to 'last 30 days' for some item-groups, from round 32 onwards, to eliminate the effects of seasonal and other transitory factors. These item-groups were clothing, footwear and durable goods for rounds 32, 38 and 43. Education and medical expenses were added to this list in round 50¹. However, only data relating to the reference period of 'last 30 days' was used for obtaining the main estimates and for measuring the incidence of absolute poverty in India (vide Report of the Expert Group of the Planning Commission, 1993). The choice of the 'last month' reference period was based on the experience gained in the early NSS rounds, especially the 4th and 5th rounds (1952-53), and some field tests carried out by Mahalanobis and Sen (1954) in rural areas of West Bengal².

Doubts were being expressed from time to time about the suitability of the 'last month' reference period. Accordingly, a Pilot Survey was conducted by NSSO in 1986-87 in rural and urban areas of five states to examine, among other things, the quality of data collected by interview method with 'last month' or 'last week' as reference period, comparing such data with data collected through daily visits to sample households for three or four consecutive days with weighment, if possible, for cereals and pulses consumed. Unfortunately, due to processing problems, no results have so far been made available for this pilot study.

In the meantime, under the influence of Professor Pravin Visaria, late Chairman, Governing Council of NSSO, comparative studies of 'last week' and 'last month' reference periods were carried out through the annual (thin sample) enquiries of consumer expenditure conducted during NSS rounds 51 to 54 (i.e., during July 1994 – June 1998). In each of these rounds, two types of schedules were canvassed in two half-

* A few early results of this Pilot Survey were reported in a paper entitled, "Impact of Reference Periods on Measuring Household Consumption: Preliminary Results of a Pilot Survey", presented to the International Seminar on "Understanding Socio-Economic Changes through National Surveys", organized by the NSSO, 12-13 May 2001, at New Delhi, as part of the Golden Jubilee celebrations of NSSO. More detailed results were later presented to the Workshop on Poverty Measurement, Monitoring & Evaluation, organized by Planning Commission, India and the World Bank at New Delhi on 11-12 January, 2002.

¹ The interviews of sample households were evenly staggered over the survey period of one year.

² Vide Appendix 1 for details of these early studies.

samples of the sample of households. In schedule type 1, the reference period was 'last 30 days' for all items of the budget, while in schedule type 2, the reference period was 'last 7 days' for food, pan, tobacco and intoxicants; 'last 30 days' for fuel and light, misc. goods and services and medical (non-institutional); and 'last 365 days' for five item groups, namely, clothing, footwear, durable goods, education and medical (institutional). The major finding from these rounds was that the week-based estimates were about 30% higher than the month-based estimates for items of food, pan, tobacco and intoxicants vide NSS Report No. 447 (Govt. of India, NSS Organisation, 2000).

In NSS 55th round (1998-99), two different reference periods – 'last 7 days' and 'last 30 days' – were employed to collect data on consumption of items of food, pan, tobacco and intoxicants, for every sample household. For the other items of the budget, the reference periods were the same as in schedule type 2 of rounds 51 to 54. The use of two reference periods for collecting information from the same sample households considerably narrowed down the differences between the week-based and month-based estimates for food, pan, tobacco and intoxicants, raising serious questions about the inter-temporal comparability of both sets of estimates.

Studies by Mukherjee and others (1974,1981) and by Minhas and others (1986,1988, 1989) had shown reasonable agreement between NSS-based estimates of aggregate household consumption expenditure and NAS estimates of private consumption expenditure upto the year 1977-78 (NSS 32th round). However, in later years, the NSS-based figures appeared to have fallen way below the corresponding NAS-based figures.

All these have important implications for measurement of inter-temporal changes in poverty and level of living in the country.

In this background, at the instance of Professor Visaria and the Governing Council of NSSO, another Pilot Survey was conducted by NSSO in five states of India, including the 4 big cities, during January-June 2000, under the guidance of an Expert Group set up by Department of Statistics & Programme Implementation, Government of India, to study, among other things, non-sampling errors in NSS consumer expenditure data. The field work was done by Field Operations Division of the NSSO and the data processing was done mainly at the Data Processing Centre of Data Processing Division of NSSO at Bangalore. Planning and the designing of schedules and tabulation and reporting of results was done by Survey Design and Research Division of NSSO at Kolkata. The aim here is to present the report on the results of this Pilot Survey.

Section 2 outlines the design of the pilot survey; and Section 3 gives a brief report on the field work stressing the extent of co-operation received from sample households. The main findings of the survey, including the key tables, are presented in Section 4. Section 5 concludes the report with some discussion on related issues. Appendix 1 contains a note on some early studies on reference periods. Appendix 2 presents the Schedule 1.0(D3/D4) used for collecting data for 'day' reference period. Finally, Appendix 3 shows some detailed tables based on pilot survey data.

2. Design of the Pilot Survey

The main objective of this pilot survey was to collect data on household consumption with three different reference periods – viz., 'last month', 'last week' and

‘day (or yesterday)’, for items of food, pan, tobacco and intoxicants, with a view to ascertaining the most suitable reference period for collecting data on these items.

The pilot survey was carried out during January – June 2000 (strictly, from 2 January to 9 July 2000) in five States, namely, Haryana, Orissa, Maharashtra, Tamil Nadu and Uttar Pradesh. In each of these states, both rural and urban areas were covered. However, owing to constraints of resources, the pilot survey was conducted in only one or two NSS regions in each state, purposively selected on the basis of region-wise poverty estimates furnished in Dubey and Gangopadhyay (1998)³. Note that in the urban sector, the study was extended to Kolkata and Delhi, besides Mumbai and Chennai, which belonged to the states of Maharashtra and Tamil Nadu, respectively. This was done with the intention of comparing the results for the four big cities (metro urban) with those for other urban areas (non-metro urban).

The state-regions selected for this pilot survey are listed below, along with their codes (these codes have recently been changed) used in Tables A8 and A9 in Appendix 3.

code	name of state-region	no. of sample households		
		Sch. 1.0(M)	Sch. 1.0(W)	Sch. 1.0(D)
082	Haryana: Western	96	96	192
311	Delhi (only metropolis)	48	48	96
253	Uttar Pradesh: Central	144	144	288
254	Uttar Pradesh: Eastern	144	144	288
145	Maharashtra: Inland Eastern	96	96	192
141	Mumbai (only metropolis)	48	48	96
192	Orissa : Southern	96	96	192
263	Kolkata (only metropolis)	48	48	96
234	Tamil Nadu: Inland	96	96	192
231	Chennai (only metropolis)	48	48	96

A two-stage stratified sampling design was adopted taking 1991 census villages as fsu’s in the rural sector and UFS blocks in the urban sector. Households were the second stage units in both the sectors.

In the rural sector, the entire rural area of each NSS region was treated as a separate stratum. In the urban sector, each of the four big cities constituted a stratum by itself, while the remaining urban areas of each region formed a stratum.

The sample fsu’s from each stratum were selected in the form of two independent sub-samples of equal size by css (a) with pps (size being measured by population) in the rural sector and (b) with equal probability in the urban sector. Fsu’s in the frame of any rural stratum were arranged as in 1991 census. Following usual procedures, a large village (or block) was subdivided into a suitable number of hamlet-groups (or sub-blocks) having equal population content and one of them was selected at random for the survey.

The total number of fsu’s in the sample was as follows: rural areas – 96 villages, 4 big cities (48 blocks) and other urban (72 blocks).

All households in a sample village/hamlet-group in the rural sector were listed

³ The region-wise head-count ratios of poverty during 1993-94 based on the Official Poverty Line (OPL) varied from 22 to 74 per cent across the rural regions and from 2 to 41 per cent for the urban regions chosen for the pilot survey.

and then arranged by the household's means of livelihood code x land possessed ascertained at the time of listing. In the urban sector, all households in a sample block/sub-block were listed and then arranged by mpce (monthly per capita expenditure) of the households ascertained at the time of listing. In each sample village/block, 16 households comprising 4 groups each consisting of 4 consecutive households in the arrangement were selected for the survey. Each group of 4 consecutive households was selected for canvassing 4 different schedules – one each for Schedule 1.0(M), Schedule 1.0(W), Schedule 1.0(D3) and Schedule 1.0(D4). In both the sectors, the first household of each group was selected by a slight modification of linear systematic sampling and Schedule 1.0(M) was canvassed for that household. The three following households of the group were canvassed for Schedule 1.0(W), Schedule 1.0(D3) and Schedule 1.0(D4), respectively. The following indicates the scope and content of each of these schedules.

Schedule 1.0(M): This was similar to the NSS 55th round schedule for collecting consumer expenditure data by interview method. The reference period was 'last 30 days' for food, pan, tobacco and intoxicants, fuel and light, misc. goods and services including medical (non-institutional), but 'last 365 days' for five remaining items groups, namely, clothing, footwear, durables, education and medical (institutional).

Schedule 1.0(W): This was similar to the NSS 55th round schedule for collecting consumer expenditure data by interview method employing 'last 7 days' as reference period for food, pan, tobacco and intoxicants. For the rest of the items, the reference periods were the same as in Sch. 1.0(M).

Schedule 1.0(D3)/Schedule 1.0(D4): These were consumer expenditure schedules with 'yesterday' as reference period for collecting data on items of food, pan, tobacco and intoxicants only, by visiting the household on three consecutive days (for Sch.1.0 (D3)) or on four consecutive days (for Sch. 1.0(D4)) vide Appendix 2. Hopefully, such data should be free from memory errors, to a large extent. For households canvassed for Sch. 1.0(D3 or D4), the interview method was followed, but special efforts were made to collect accurate data through daily interviews and by measurement for key items, as far as possible. First, each household was supplied with notebook and dot pen and requested to keep a record of consumption of each spending member of the household. More importantly, each household was supplied with two transparent graduated containers with volume markers, one measuring 500 ml and the other 100 ml, and they were urged to measure out cereals and cereal products, pulses and pulse products and liquid milk consumed each day using these containers instead of their own containers⁴. For salt, with a view to obtaining accurate figures, each household was requested to consume from one or more 0.5 kg packets of salt supplied to them. The quantity of salt left unused at the end of 3 or 4 days was weighed to estimate the quantity of salt consumed over the period. The day was taken from midnight to midnight.

The focus of the present Pilot Survey was on the choice of appropriate reference period for items of food, pan, tobacco and intoxicants. Schs. 1.0 (D3/D4) were designed to record consumption of only these items and to obtain such data as accurately as possible. Schs. 1.0 (M)/ 1.0 (W), however, were the conventional schedules and included all items of the budget. This was done to ensure that normal conditions under which NSS

⁴ The conversion factors from ml to kg were determined by the field workers for different items separately for each NSS region.

enquiries through Sch. 1.0 are carried out prevailed at the time of canvassing these two schedules.

In the daily schedules, Schs. 1.0(D3/D4) - see Appendix 2 - there were columns for recording volume of consumption (in ml), using one or the other of the containers supplied by NSSO staff, for each item of cereals and pulses and their products and for liquid milk. The measurements were to be taken after shaking the container, leveling the contents and slightly pressing the contents, if necessary. Conversion factors were then used to convert these volumes into quantity figures in standard unit (kg). These conversion factors were estimated by field staff of NSSO, separately for each item and for each NSSO FOD region under study. In those cases where quantity of consumption could be reported in standard units by the respondent, this quantity was entered in the schedule, in a column earmarked for the purpose.

For several items in Sch. 1.0(D3/D4), like spices, the quantity/volume of consumption tended to be small for any particular day, and field workers were asked to enter the total quantity/volume of consumption for the 3 or 4 day period on the last day.

The number of sample households per fsu (village/block) was 4 for each of Schedules 1.0(M), 1.0(W), 1.0(D3) and 1.0(D4). Thus, the total number of sample households allotted for the Pilot Survey was 864 for each of the four schedules. The corresponding total number of daily schedules would be 2592 for Sch. 1.0(D3) and 3456 for Sch. 1.0(D4).

The interviews (and measurements) for schedules with different reference periods were evenly spread (during each month of the six-month period) over the days of the week and the weeks of the month to ensure that the results based on Sch. 1.0(W) or on Sch. 1.0(D3/D4) are meaningful and comparable with results based on Sch 1.0(M). The detailed programme of filling up the four schedules were laid down in the instructions and was generally followed by the field staff. This was done as far as possible for each State x sector x stratum⁵.

Tables A3 to A7 in Appendix 3 depict the quality of matching of the three samples of households canvassed for the three reference periods. For reasons of space, the results are presented for all States and regions combined, though separately for the three sectors. It may be seen that the three samples of households agreed fairly well in respect of average household size and also in respect of their distributions over categories by household type (broad household occupation), by religion, by social group and by size of land holding (in rural sector).

3. A Brief Report on Field Work

At the outset, the investigators explained the objectives of this Pilot Survey to all respondents, especially those chosen for Schs. 1.0 (D3/D4), and appealed for their co-operation.

There were only a few casualties for the four schedules. The number of households actually canvassed is shown below by sectors and by type of schedule:

⁵ Tables A1 and A2 in Appendix 3 show the distribution of sample households canvassed for each type of Schedule over the different months and over different weeks of the month.

sector	number of households canvassed by type of schedule*		
	Sch. 1.0 (M)	Sch. 1.0 (W)	Sch. 1.0 (D3/D4)
rural	384 (384)	383 (384)	768 (768)
non-metro	288 (288)	288 (288)	574 (576)
metro	188 (192)	187 (192)	384 (384)
total	860 (864)	858 (864)	1726 (1728)

* Number of households allotted for the survey are shown within brackets.

Further, no information on salt consumption could be collected for a small percentage of households canvassed for Sch. 1.0 (D3/D4)

The overall experience of field work was that relatively affluent households were less cooperative than poorer households and found the use of containers too time-consuming. The less educated informants could not record the details in the diary very well. Regarding salt, some households did not accept salt as they were not accustomed to the use of powdered salt of the kind supplied by NSSO. However, some of them gave reliable data because the opening stock of salt used by them and the balance left on the last day could be measured.

Daily visits for 3 or 4 consecutive days were not liked by some households. Also for both Schs. 1.0 (M) and 1.0(W) many informants looked tired and reluctant towards the end of the interview. According to entries made by the investigators in the schedules, the average time taken (in minutes) for canvassing the different types of schedules was as follows:

	Sch. 1.0(M)	Sch. 1.0(W)	Sch 1.0(D3)/Sch 1.0(D4)
rural sector	182	175	125 (per day)
non-metro urban	179	173	117 (per day)
metro urban	177	170	90 (per day)

Clearly, the 'day' schedules were canvassed with maximum care.

There was some variation across NSS regions in the average time taken to canvass the schedules. This could be attributed to factors like literacy level of the informants, income/consumption level of the households, extent of co-operation of respondents and the number of visits needed to canvass the schedule.

For some items like pulses the quantities consumed on a day were small and there could be large errors, in relative terms, in the measurements with the container. For liquid milk, the poorer households consumed very small quantities of milk and did not use the container.

Tables 1 to 3 present some information on the extent of cooperation received from households responding to Schs.1.0 (D3/D4). As stated earlier, all the 1728 sample households, excepting only 2, were canvassed.

Table 1 shows that out of 1728 sample households selected for collection of data through daily Sch.1.0 (D3/D4) as many as 1544, i.e., about 89%, accepted the packet(s) of salt supplied to them by field workers of NSSO in the interest of collecting accurate data on consumption of salt. This percentage was higher, about 95, for the rural households, but appreciably lower, around 76, for the 4 big cities; for the other urban areas, this percentage was roughly the same as the overall figure, about 90.

Table 1 : No. of sample households accepting salt supplied by field staff of NSSO

sector	hhs for Sch.1.0(D3)		hhs for Sch.1.0(D4)		percentage of hhs accepting salt	
	total no. in sample	no. accepting salt	total no. in sample	no. accepting salt	Sch.1.0(D3)	Sch.1.0(D4)
					(6)	(7)
(1)	(2)	(3)	(4)	(5)	(6)	(7)
rural	384	362	384	365	94	95
non-metro	288	266	288	261	92	90
metro	192	145	192	145	76	76
all	864	773	864	771	89	89

Table 2 presents the frequencies with which the two containers supplied by NSSO staff were actually used by sample households selected for Sch.1.0(D3/D4) for measuring out consumption of different items. Only the major items are shown in the table. (Similar figures for the detailed items are presented in Table A8 of Appendix 3.) The counts refer to the number of daily schedules, and not to the number of households. It appears that for most of the important items, the households co-operated to a great extent, and 80 to 90% of them reported that they had used the containers wholly for the measurements. There are, however, exceptions to this general pattern. Many of the items showing deviations from the general pattern are not very important, except for liquid milk. Here, about 45 to 50 per cent of the households in rural and non-metro sectors but only about 13 per cent of the metro households had used the containers wholly for the measurements. These low percentages for liquid milk could be explained by the fact that many households had obtained their milk supply from outside and depended on the volume measurements made at that stage.

Closer examination shows inter-sectoral differences in the extent of use of containers. On the whole, rural households reported that the containers had been wholly used in a much higher proportion of cases than their counterparts in metro (urban) sector, with households in non-metro(urban) occupying an intermediate position.

Table 3 shows the number of households selected for Schs. 1.0(D3/D4) that had complied with the request made by NSSO staff to record daily consumption in a diary supplied to them. It appears that roughly about half of the sample households in rural and non-metro sectors had used the diary quite often and that in this matter, households in the metro sector had co-operated to a smaller extent.

Data on the number of meals consumed by persons other than the usual members of the households were examined, and it was found that such meals were relatively small in number and did not materially influence the results (vide Table A11 in Appendix 3).

Table 3: Percentage of daily schedules reporting use of diary for recording daily consumption in Sch.1.0 (D3/D4)

sector	% of daily schedules reporting use of diary				no. of daily schedules
	quite often	a little	not at all	not recorded	
(1)	(2)	(3)	(4)	(5)	(6)
rural	52.9	24.6	18.9	3.6	2688
non-metro	50.2	26.8	15.3	7.7	2016
metro	36.0	33.5	25.4	5.1	1344
all	48.3	27.3	19.1	5.3	6048

4. Main Findings of the Pilot Survey

Tables 4 and 5 present the main results of the Pilot Survey. Table 4 shows estimates of consumption in quantity and value terms, per person per 30 days, for some important items and item-groups. With the exception of potato, these were the items or item-groups for which attempts had been made to collect relatively accurate data through the use of containers (or packets of salt) supplied by NSSO staff. Three sectors are distinguished, namely, rural areas, the four big cities (metro) and other urban areas (non-metro), as the differentials across the three reference periods can conceivably vary across these sectors. For the sake of interest, the table also shows the number of sample households reporting each item or item-group. Overall results for the urban sector were obtained as weighted averages of estimates for non-metro urban and metro urban, using weights 255 and 31, respectively, based on 2001 census populations of the two sectors for the country as a whole. Results for all-India rural plus urban were similarly computed using weights rural : urban as 742 : 285.

Table 5 is similar to Table 4, but covers other item groups under food, pan, tobacco and intoxicants, and does not show any estimates of quantity⁶.

⁶ Regionwise estimates parallel to those presented in Tables 4 and 5 are shown in Tables A9 and A10 of Appendix 3. Estimates for *all* individual items under food, pan, tobacco & intoxicants are placed in Table A13 of Appendix 3.

Both Tables 4 and 5 present the estimates separately by sub-samples and also for the combined sample. The divergence between sub-sample estimates indicates the margin of uncertainty associated with the combined estimate.

The sub-sample estimates show a good deal of divergence and so, sampling errors being large, some of the differentials across three reference periods observed from Tables 4 and 5 may not come out significant by strict statistical tests. This is confirmed by Tables A9 and A10 in Appendix 3 which show region-wise estimates, separately for three sectors. In principle, one might examine region x sub-sample-wise estimates, but such examination appears to be hardly necessary. The sub-sample-wise and region-wise estimates give a fairly good idea of the variability of the material and hence of the statistical significance of the differentials across 'last month', 'last week' and 'day (= yesterday)' reference periods.

Table 4 suggests that “last month” estimates may be closer to the “day (or yesterday)” estimates compared to the “last week” estimates for several items or item groups covered in Table 4, but this superiority is seen only for one or two of the three sectors, while “last week” is found to be closer for the remaining sector or sectors. Only for cereals and products, “last month” seems to be appropriate for all three sectors. The following is a tentative summary of conclusions which might be drawn from the quantity estimates in Table 4:

item/item group	appropriate reference period by sector				
	rural	non-metro urban	metro urban	urban	rural plus urban
rice and products	month/week	month	month	month	month
wheat and products	week	month	week	month	month
cereals and products	month	month	month	month	month
pulses and products	week	week	month	week	week
milk(liquid)	week	month	week	month	month/ week
sugar group	week	month	month/ week	month	month/ week
salt	month/ week	month/ week	month/ week	month/ week	month/ week
edible oil	week	week	month	week	week
potato ⁷	week	week	week	week	week

While figures in Table 4 do not show “last month” in a very unfavourable light, those in Table 5 do so in no uncertain terms. The week-based estimates of expenditure or value of consumption are, by and large, appreciably higher than the corresponding month-based estimates and are generally much closer to the day-based estimates. This shows that “last week” would be more appropriate than “last month” in many cases.

Table 6 brings out the fairly systematic differentials between week-based and month-based estimates of value of consumption for different groups of items under food, pan, tobacco and intoxicants.

The following conclusions may be drawn from Tables 5 and 6 regarding the estimates of value of consumption:

- (i) For food group, as a whole, week-based estimates appear to be higher than month-based estimates by 23% for rural areas and by 16% for non-metro urban sectors; however, for the metro sector the difference seems to be negligible. These differences are about 14% for the urban sector and 21% for rural plus urban.

⁷ The conclusion for potato is in keeping with that for vegetables group.

- (ii) The day-based estimates appear to be even higher. Table 7 expresses the month-based and week-based estimates of value of consumption as percentages of corresponding day-based estimates. Compared to the week estimates the day estimates for all food seem to be higher by 7% for the rural sector, by 7% for non-metro urban and by 11% for metro urban. For rural and urban sectors combined, this difference is about 8%.
- (iii) For most of the items, week estimates are appreciably higher than corresponding month estimates for all the sectors. There are, however, exceptions.

Thus, for milk and products, the week-month differences are not clear for any sector.

For the metro sector, the week-month differences are not clear for pulses and products, edible oil, egg, fish & meat, sugar, salt, beverages etc. and tobacco.

For tobacco, the differential is not clear for non-metro urban as well.

For intoxicants, the week-month differential is not clear for rural and non-metro urban sectors.

Finally, for dry fruits, month estimates appear to be higher than week estimates for non-metro and metro urban sectors.

- (iv) Beverages etc. is one of the item-groups contributing to the large week-month differential for the rural sector. The same differential is much smaller or negligible for the other two sectors. This group is highly heterogeneous, comprising items like tea and coffee, cold beverages, fruit juice, biscuits, cake and pastry, salted refreshments, prepared sweets and cooked meals. However, even for the rural sector, the week – month differential for the food group does not change much if beverages etc. be excluded.

In Table 4, the differentials across the three reference periods appear to be slightly larger for value of consumption than for consumption in quantity terms and the conclusions might be slightly different depending on whether one considers the estimates of consumption in quantity or value terms. Table 8 was prepared to examine this matter. It presents the average prices implicit in the estimates of consumption in quantity and value terms presented in Table 4. Only the combined sample estimates are presented in this table. It appears from Table 8 that for many items and item-groups of the food group, the average implicit price was the highest for “day (or yesterday)” reference period and the lowest for the “last month” reference period, with “last week” prices occupying an intermediate position. Whether or not this pattern is illusory, created by differential reporting errors, is hard to say.

* unit of quantity is litre for liquid milk

As many of the sizeable differences in Tables 4 and 5 are not clearly significant, one might conclude that the sample sizes, that is, the scale of the Pilot Survey under report, was not sufficiently large to show up even fairly sizeable differences as statistically significant.

Nevertheless, it seems reasonable to conclude that, on the whole, for both rural and urban sectors, the 'last week' reference period would be more appropriate than the 'last month' reference period for many groups of items, e.g., vegetables, fruits (fresh),

and spices, because the week-based estimates of value of consumption appear to be *closer* to the corresponding day-based estimates, *which are taken as standard*. Similar conclusions may also be drawn for ‘all food’ group, as a whole and for pan, tobacco and intoxicants. However, for some item groups including cereals and products, which are important for nutrition-oriented studies, ‘last month’ estimates look better or reasonable and so ‘last month’ could be retained as reference period for such groups.

The finding that week-based estimates for many food items and for pan, tobacco and intoxicants obtained from this Pilot Survey are much higher than the corresponding month-based estimates is broadly similar to that based on NSS rounds 51 to 54 (vide NSS Report No. 447, Govt. of India, NSS Organisation, 2000). However, the week-month differentials seem to be narrower for this Pilot Study. The difference for salt is striking.

These conclusions differ from those of the earlier paper, “Impact of Reference Periods etc.” prepared by the NSSO Expert Group on Non-Sampling Errors which presented some preliminary results of this Pilot Survey. This earlier paper had focused on quantities of consumption of cereals and products, pulses and products, liquid milk, and items of the sugar group and salt, in an attempt to check the conclusions of Mahalanobis and Sen (1954). For most of these item groups, especially for cereals and products, the revised estimates presented in this Report indicate that the ‘last month’ reference period is fairly appropriate.

The changes in the conclusions are not hard to explain. For items of the cereals group, for example, most of the households consume only a few items of the group and consume them at a more or less fixed daily rate over the last 30 days. The problem of reporting total consumption during the last 30 days is not as serious as one might think for such items or item-groups. This is why for groups like cereals, estimates for last month are fairly close to estimates for day (or yesterday). If estimates for last week are on the higher side, this may be due to telescoping or other effects.

The problem of recall is more serious for items of groups like vegetables, fruits (fresh), spices or beverages etc. For such items, the level of consumption often fluctuates from day to day much more than for items like rice or wheat. The informant may not clearly recall on how many days of the last month his/her household consumed items like brinjal, onion, banana or biscuits, and what the quantities consumed were. Also, he may not make any serious effort to recall such facts consulting other members of the household during the hurried process of interview, the respondent burden proving to be too much. Recalling such consumption-related events during the ‘last week’ is obviously easier. Under-reporting of past consumption through recall lapse is thus likely to be smaller for item groups like vegetables when ‘last week’ reference period is used.

5. Discussion and Concluding Observations

The UN NHSCP manual on non-sampling errors (1982, see in particular pp. 134 – 5) sums up the experience on recall lapse in surveys of income and expenditure and other retrospective surveys. It states that designs using bounded recall and fairly short reference periods have become popular. In this approach, each household is interviewed for several consecutive time periods. After the first time, the interviews become dependent, because the interviewer reminds the respondent of what he had reported the last time and asks about subsequent expenditure. The first report is not included in the tabulation, but is only used for establishing the basis for subsequent interviews. These observations were

hardly meant for situations where households are interviewed for several consecutive *days*; and in this Pilot Survey, each sample household selected for ‘day’ reference period was visited on a day preceding day 1 to prepare the household for subsequent visits. Hence, data for day 1 was unlikely to be seriously affected by recall errors. Nevertheless, an attempt was made to tabulate the information collected through Schs. 1.0(D3/D4) in this Pilot Survey separately for the 3 or 4 days, to find out whether the results would change if data for day 1 were excluded in the process of estimation. Some results are presented in Table A12 in Appendix 3. It appears that the variation in estimates across the three or four days was small and inconsequential⁸.

It has long been recognized that the Indian informants, especially those in the cities, had become much busier than before, and cynical about, and somewhat resistant to, the long interview needed for canvassing the detailed NSS Schedule for Consumer Expenditure. The consumption pattern had also become more diversified. Further, events from other spheres of life had been increasingly impinging on their consciousness. So the salience of consumption-related events in their memory was no longer as clear as in the 50’s and 60’s, and the interview was imposing too great a *respondent burden* on the m by asking them to recall all such events that had occurred during the last 30 days preceding the date of interview. Moreover, thanks to improvements in roads and transport facilities, the typical field investigator was no longer setting up camps in sample villages, but was commuting daily from some nearby town and conducting the interviews at times not necessarily convenient to the informants. Therefore, many of the interviews were being conducted in a hurried manner, especially in the larger towns and cities. The use of the ‘last month’ reference period was aggravating the problem. Shortening the Consumer Expenditure Schedule is as important as choosing appropriate reference periods (vide Report of the National Statistical Commission, 2001, see p.57 of Vol. 1 and pp.278-281 of Vol. 2).

From the point of view of sampling in time, the reference period of ‘last 30 days’ nets a larger sample of consumption (expenditure) events than the reference period of ‘last 7 days’. This is why the rse’s of estimates are generally smaller for month-based estimates than for week-based estimates. Owing to the small sample sizes, the present Pilot Survey did not yield dependable estimates of rse’s for the three reference periods. We therefore reproduce in Table 9 the relevant portion of Table T2 of NSS Report No. 447 (vide Government of India, NSS Organisation, 2000) which compares rse’s of month-based and week-based estimates of per capita consumption for all-India, rural and urban, obtained from NSS rounds 52 and 53.

⁸ The figures for the last day of the three- or four-day reference period appear to be much higher than those for the earlier days, for some items/ item-groups like spices and beverages etc. For these items/ item-groups, the total consumption for the three- or four-day period was entered on the last day.

* For item groups shown here, the reference period was 'last 7 days' for schedule type 2 but 'last 30 days' for schedule type 1.

A more serious consideration is that if one adopts last week as the reference period, one has to *stagger the interviews evenly over the 52 weeks of the survey year* and not merely over the 12 months of the survey year. And this would be a severe restriction on the work programme of the field staff. Table 10 presents some figures for all-India, rural plus urban, reproduced from NSS Report No. 447 (*vide* Table T8 on p. 29) which show that during rounds 51 to 53, when no special instructions were given to the investigators about the spreading of the reference week over the calendar month for schedule type 2 – where the last week reference period was used for items of food, pan, tobacco and intoxicants, last 30 days for item groups like fuel and light, and last 365 days for item groups like education – the investigators tended to interview relatively few households during dates 1 – 7 of the calendar month⁹. Table 10 also presents figures extracted from the table mentioned above which show that average mpce (monthly per capita expenditure) of sample households could be higher when the interviewing is done during the first week of the calendar month compared to the remaining weeks of the same month. Further details may be seen from the table mentioned above.

⁹ This was mainly because the investigators drew their salaries in the first week of the month.

Table 10: Some aspects of the canvassing of Schedule type 2 during NSS rounds 51 to 53: all-India, rural plus urban

date of canvassing	no. of schedules of type 2 canvassed			average mpce of sample hhs (Rs.)		
	round 51	round 52	round 53	round 51	round 52	round 53
1 – 7	1798	1758	2026	464	556	620
8 – 14	6026	6087	4882	442	514	605
15 – 21	7256	6791	5258	440	506	616
22 – 31	10862	9431	8383	442	505	603
all	26437	24141	20601	442	511	612

The use of last week reference period may also introduce biases if weeks including festival days, say, are not covered in the right proportion.

The finding that day-based estimates are appreciably higher than even the week-based estimates cannot be ignored. However, the adoption of ‘day or yesterday’ as reference period for the nation-wide surveys conducted by NSSO seems to be infeasible. Cost would be manifold, and co-operation of the kind received in this Pilot Survey from the informants cannot be guaranteed in repetitive surveys. Repeated interviews for the same household for three or four consecutive days and collection of data on volume of consumption through containers would not be possible on any large scale year after year. One suggestion is that NSSO may consider conducting small-scale enquiries at suitable intervals to monitor the divergence between day-based and week-based estimates. It is, however, possible that the day estimates obtained in this Pilot Survey were on the high side, through one or other type of bias.

For the sake of completeness, we may make a few observations on the choice of appropriate reference periods for item-groups of the household budget other than food, pan, tobacco and intoxicants. Field tests as well as analytical studies seem to be necessary for making these choices. In the experiments with two types of schedules in rounds 51 to 54 mentioned in Section 1, ‘last 30 days’ was adopted in both schedule types for fuel and light, misc. goods and services, and medical care (non-institutional). These groups do not seem to pose any special problem. For clothing and footwear, the advantages of adopting ‘last 365 days’ as reference period instead of ‘last 30 days’ seem to be clear, and in the experiments with two types of schedules in rounds 51 to 54, the estimates were not very different for the two reference periods. Therefore, the longer reference period with a lower rse is more appropriate, considering its stabilizing effect on seasonal and other short-run fluctuations. There are, however, problems for the groups of education, medical care (institutional) and durables. The estimates from rounds 51 to 54 showed that for these three item groups, ‘last month’ gave appreciably higher figures than ‘last year’, the difference being 26% for education, 41% for medical care (institutional) and 44% for durable goods. The drop in rse when ‘last year’ is used cannot compensate for such downward bias in the estimates. There are, however, doubts about the quality of data collected in rounds 51-54, and checks against NAS figures appear to be important.

Note that the use of ‘last 365 days’ instead of ‘last 30 days’ as reference period for item groups like clothing, footwear etc. provides a more stable measure of monthly per capita consumer expenditure (mpce) and shifts the Lorenz curve of mpce inward vide NSS Report No. 384 (Government of India, NSS Organisation, 1992). A more subtle effect is that if Engel curves are estimated by regressing per capita item consumption on mpce, then Engel elasticities for items like clothing change appreciably if the mpce is computed utilizing annual expenditures on item groups like clothing and footwear instead of last month expenditures on these item groups (see Ghose and Bhattacharya, 1994).

Appendix 1: A Note on Some Early Studies on Reference Periods

In the 4th and 5th rounds of NSS, conducted during 1952-53, it was decided to compare the 'last week' and 'last month' reference periods for ascertaining the correct volume of consumption of food and a few other items. Two schedules with two reference periods, 'last month' and 'last week', for these items, but otherwise identical, were used. The sample households allotted to each investigator were divided into two sub-samples and for one of them the weekly schedules were completed and for the other the monthly schedules were completed. In view of the importance of the question, two investigators were sent to each village to investigate a different sample of households and thus to obtain replicated data. Hence, for any sample village, readings for a weekly period and a monthly period were obtained from each of the two investigators. It was then seen that the figures obtained for the 'last week' reference period were higher than the figures obtained with 'last month' as reference period. However, the degree of difference between the two sets of estimates did not manifest consistency over the two rounds except for foodgrains (cereals plus cereals substitutes), where the week estimates were about 7 per cent higher in rural areas and about 11-12 per cent higher in urban areas, in both the rounds compared to month-based estimates. For all food, the same differences were found to be as follows:

rural		urban	
4 th round	5 th round	4 th round	5 th round
10.4	22.3	13.7	14.4

The special study by Mahalanobis and Sen (1954) described below was carried out to settle the question as to which of the two reference periods was giving the more correct figures.

The Mahalanobis and Sen special study was conducted in March-April 1952 in 76 villages in West Bengal. A total of 1254 sample households were selected from these villages and these were divided into four sub-samples. Items under study were clean rice, pulses, sugar and salt. Information was collected from the first and the second sub-samples of households by interview method, using last week and last month reference periods, respectively. For the two remaining sub-samples, particulars of consumption were obtained by actual weighing of these food items by the investigators. The investigators requested the households to place the supplies for about 10 days in some suitable receptacles and to draw from these stocks for consumption during the next 7 days. The investigators weighed the opening stock and also the balance left a week later. In the third group of households, the weighing was done with an interval of 7 days, while for the fourth group, the weighing was done twice in 7 days. These operations were repeated for three weeks. The starting days of the 7-day periods for the different households were scattered over the different days of the week. The study showed that the figures obtained through interviews with last month as reference period agreed fairly well with those based on weighing, while the figures based on last week were appreciably higher. This could have been due to border effects or telescoping in reporting food consumption during the last week (see also UN National Household Survey Capability Programme, 1982, pp. 127-129).
