# THE NATIONAL SAMPLE SURVEY

NINETEENTH ROUND : JULY 1964—JUNE 1965

NUMBER 133

## SOME RESULTS OF THE LAND UTILISATION SURVEY AND CROP-CUTTING EXPERIMENTS

*Issued by :*

THE CABINET SECRETARIAT  
GOVT. OF INDIA

#### **ACKNOWLEDGEMENT**

The report was finalised by S. Bhaskaran Pillai and Rajagopal Sarma. N. G. Pramanik, N. K. Dasgupta and S. C. Basu Roy were associated in the work relating to the preparation of the report.

Supervision of computing and tabulation was entrusted to S. S. Bose, N. B. Chowdhury, A. K. Chowdhury and S. K. Palit.

The design of the survey was prepared by the Indian Statistical Institute.

The primary data were collected by the Directorate of the National Sample Survey, Government of India, in all the states except in West Bengal where the Indian Statistical Institute collected the data.

## NATIONAL SAMPLE SURVEY

NINETEENTH ROUND : JULY 1964—JUNE 1965

Number 133

### Some results of the land utilisation survey and crop-cutting experiments

The report entitled 'Some results of land utilisation survey and crop-cutting experiments, 19th round, July 1964—June 1965' was prepared by the Indian Statistical Institute. The views contained in the report are not necessarily those of the Government of India.\*\*

#### CHAPTER I

##### INTRODUCTION

1.1 As in earlier years the land utilisation survey and crop-cutting experiments were conducted in 1964-65 as part of the 19th round of the National Sample Survey in order to obtain an all-India estimate of production of the seven major cereal crops (rice, jowar, bajra, ragi, maize, wheat and barley) for the agricultural year 1964-65 as a whole. In this round the scope of the survey was extended so as to obtain all-India estimates of area under small millets also. It may be mentioned that since for small millets crop-cutting experiments were not planned production estimates could not be obtained for this crop. The survey in this round was also planned to obtain estimates of production of important cereal crops at state-level by pooling central and state samples.\*

1.2 *Period of survey.*—The survey started in July 1964 and ended in June 1965.

1.3 *Geographical coverage.*—The survey was carried out in the whole of rural India excluding Andaman and Nicobar Islands, Laccadive, Minicoy and Amindivi Islands, Ladakh district of Jammu and Kashmir, the North East Frontier Agency, Mao, Ukhru and Tamenlong sub-divisions of Manipur and the Union Territories of Goa, Daman, Diu and Pondicherry.

1.4 *Sample design.*—For the land utilisation survey a stratified two stage design with 4 independent sub-samples was adopted with villages as first stage units and clusters of plots as second-stage units. For yield survey a multistage design was adopted, with villages, clusters of plots, sub-plots growing specified crops and circular cuts of radius 4' as successive sampling units. In each of the four seasons, autumn, winter, spring and summer which comprise one agricultural year, 8472 sample villages were planned to be surveyed for area enumeration. The 8472 villages for area survey was in the form of 4 independent sub-samples of 2118 villages. Sub-samples 1 and 3 were surveyed by one party of investigators and 2 and 4 by another party. Crop-cutting experiments were planned in each season in one half of the villages of sub-samples 1 and 2 only; that is in a total of 2118 villages.

1.5 *Method of collection of data.*—Data on land utilisation were collected by direct physical observation of the utilisation in sample plots. Generally 4 clusters of 5 plots each were selected in each village for this purpose. In villages where crop-cutting experiments were also to be carried out, 6 clusters of 10 plots each were selected for land utilisation survey. Each sample village was visited in proper time for each season after the sowing of the crops of the particular season in the sample village was completed and when harvesting of crops of that season had not started, that is, when the crops were unmistakably identifiable. Data on yield were collected by harvesting a circular area of radius 4 feet located at random in a field when the crop was ready for harvesting. In actual practice the data were collected in two stages, first from a circle of radius 2'-3" and then from the annular portion between the circles of radius 2'-3" and 4'. The yield of crop from the smaller circle was used for driage experiments to estimate the conversion (driage) factor to be used to obtain the yield of dry crop from that of green crop.

1.6 *Scope of the report.*—This report deals with the results of the survey on the basis of the data collected in the central sample. The All India estimates of gross area and production of the seven major cereal crops and also the estimated gross area under small millets for 1964-65 are given in this report. Besides the estimates of production and gross area are also given at state-level for some selected crops and states. Chapter 2 deals with some of the concepts and definitions used in the survey. Chapter 3 contains a summary of the main results of the survey. Chapter 4 gives some of the statistical tables which include tables giving season-wise estimates of area and production at all India level and unweighted yield rates at state level of the seven cereal crops separately for pure and mixed cultivation and for irrigated and non-irrigated crops. A note on the sampling design and estimation procedure is given as Appendix I. A facsimile of the schedules of investigation forms Appendix II.

1.7 It may be mentioned that the season-wise estimates for 1964-65 were made available to the Government progressively as soon as tabulation for a particular season was completed. The estimates for the whole year 1964-65 were sent to the Government in October 1965.

\*In the NSS programme of work, most of the State Governments are participating on a matching basis. At state-level the field work in half the number of total villages designated as Central sample is done by the Directorate of NSS and in the remaining half designated as State sample by the staff of the participating State Govt. The sampling scheme, concepts, definitions and procedures followed are identical for the Central and State samples.

\*\*The draft report (No. D. 161) was first submitted by The Indian Statistical Institute, Calcutta, to the Government of India in March, 1967. It was revised subsequently and resubmitted in November, 1967.

## CHAPTER 2

### CONCEPTS AND DEFINITIONS

2.1 Some of the important concepts and definitions used in the survey are described below.

2.2 *Sample village*.—A revenue village corresponding to the selected census village (which constitutes the primary sampling unit) was taken as the sample village for land utilisation survey and crop-cutting experiments. Generally, the revenue village and census village were identical, but in some cases the two were not identical. When the selected census village was a part of a revenue village, the whole of the revenue village was surveyed. If on the other hand, the census village was formed by more than one revenue village, one of the revenue villages was chosen at random with equal probability for the purpose of the survey.

2.3 *Season*.—For each of the crops grown in a village, appropriate season was assigned on the basis of the period of harvesting of the crop in the village in a normal year. The months of harvesting in a normal year corresponding to the different seasons are given below :

season of the crop	normal months of harvesting	
	1	2
autumn . . . . .	August to October	
winter . . . . .	November to January	
spring . . . . .	February to April	
summer . . . . .	May and June	

NOTE :—July was taken to correspond to summer or autumn depending on the crop and region.

When harvesting of a crop in a normal year was spread over two seasons, the crop was assigned to that season which covered the greater part of the harvesting period.

2.4 *Proper time of visit for land utilisation survey and crop-cutting experiments*.—The land utilisation survey was carried out in a village in proper time with respect to cereal and pulse crops for each of the seasons autumn, winter, spring and summer. The proper time for area survey for a season was the period when the sowing of all the crops of that season had been completed but harvesting had not yet started and the crops were unmistakably identifiable. Crop-cutting experiments were carried out when the crop was ripe and ready for harvesting in the selected fields.

2.5 *Plot*.—For the purpose of the enquiry, a plot was defined as a distinct patch of land generally having a major survey number.

2.6 *Pure crop and mixed crops*.—When only one crop was grown in a patch of land, it was considered as growing pure crop. A patch of land which was growing two or more crops in intermixture was taken to be under mixed crops. In case of mixed crops, the components might be sown (or harvested) at the same time or at different times. Sometimes the components might be at different stages of growth (e.g. one of the components might be harvestable while others might be just sprouting up from the ground). When a crop was grown in an orchard, it was considered to be under mixed crops. Also crops grown in alternate strips, each of width less than 8' were treated as mixed crops.

2.7 *Sub-plot*.—In a plot, a distinct patch growing a crop or a particular mixed crop was treated as a sub-plot (field). A plot was considered to have as many sub-plots (fields) as there were different patches growing the crops singly or in mixture.

2.8. *Ail or bund*.—A plot is demarcated generally by a strip of raised land commonly known as ails or bunds. Besides these, there may be ails inside the plot. Some of these inside ails are more or less of a permanent nature having almost the same height as the boundary ails. These inside ails were treated in the same manner as boundary ails.

2.9 *Gross area under a crop*.—If a patch of land was under a mixed crop the total area under the mixed crop was taken to be the gross area under each of the components of the mixed crop. When a crop was grown pure in a patch of land the gross area under the crop was the same as the area under the crop.

## CHAPTER 3

### SUMMARY OF RESULTS

**3.1** The main results of the survey—estimates of production and gross area under crops together with sample size—are given in this chapter. A comparative table giving the estimates for 1964-65 and for 1963-64 (the latter obtained from the 18th round of NSS) is also given. A comparison of the NSS estimates of production and the corresponding estimates from the non-NSS official series is also made.

**3.2** *Number of villages surveyed and number of crop-cutting experiments conducted.*—Table (3.1) gives the number of sample villages surveyed for land utilisation survey and crop-cutting experiments and table (3.2) gives the number of crop-cutting experiments conducted on the seven major cereal crops.

**TABLE (3.1)** *Number of villages allotted and surveyed for land utilisation survey and crop-cutting experiments.*

**3.3 Estimates of production and gross area.**—As has been mentioned in Chapter I (and explained in detail in Appendix), land utilisation survey was conducted in 4 sub-samples, while crop-cutting experiments were planned only in sub-samples 1 and 2. The villages of sub-samples 1 and 3 were surveyed by one party of investigators and those of sub-samples 2 and 4 by another party. The total sample made up of sub-samples 1 and 3 is designated as half-sample 1 and sub-samples 2 and 4 as half-sample 2. The production estimate for half-sample 1 have been obtained on the basis of the area estimates built up from sub-samples 1 and 3 and the yield rate from sub-sample 1. Similarly production figures for half-sample 2 are based on area estimates from sub-samples

2 and 4 and yield rate from sub-sample 2. The estimated production of each of the seven major cereal crops in rice, jowar, bajra, ragi, maize, wheat and barley for all India for the year 1964-65 are given below in Table (3.3).

TABLE (3.3) *Estimated production in thousand tonnes of the major cereal crops, 1964-65*

ALL-INDIA

crop	half-sam-	half-sam-	combined
	ple 1 (sub- samples 1 and 3 combined)	ple 2 (sub- samples 2 and 4 combined)	
(1)	(2)	(3)	(4)
rice . . . . .	39940	37888	38913
jowar . . . . .	11401	11305	11355
bajra . . . . .	3804	4739	4270
ragi . . . . .	2070	1941	2005
maize . . . . .	4820	6066	5444
wheat . . . . .	14583	15302	14992
barley . . . . .	3242	2751	2998
total . . . . .	79960	79992	79977

The production figures for rice relate to clean rice. The factor 0.662 has been used to convert yield of dry paddy to that of clean rice.

## CHAPTER 4

### STATISTICAL TABLES

4.1 Some statistical tables relating to the survey are given in this chapter. The number of sample villages planned and number surveyed for land utilisation survey and for crop-cutting experiments are given for each state and season. The number of crop-cutting experiments conducted on each crop separately for pure and mixed crop are given by states and seasons. Table (11) gives the all-India estimates of area and production for each season by sub-samples. The estimates of production and area at the state level are given in table (12) for some selected crops and states. Tables (13) to (19) give the unweighted yield rate of the seven crops under pure and mixed categories. The yield rates of crops separately for irrigated and non-irrigated crop are given in tables (20) to (26).

4.2 It may be mentioned that the total number of cuts on which the yield rates given in tables (13) to (26) are based does not tally with the total number of cuts on which the production estimates are based and which are given in the earlier tables. This is due to (1) data on irrigation particulars were not available in a few cases and hence they were excluded for calculation of unweighted yield rates and (2) a few schedules received late from the field, which were not included for estimating production of crops were subsequently included for calculation of unweighted yield rates.

## APPENDIX 1

### SAMPLING DESIGN AND ESTIMATION PROCEDURE

The sample design was a stratified two-stage one for the land utilisation survey, villages being the first stage units and clusters of plots\*, the second stage units. For yield survey, the design was a four-stage one with villages, clusters of plots, sub-plots\*\* growing specified crops and circular cuts of radius 4 feet as the first, second, third and fourth stage units respectively. The first stage units were selected in the form of 4 independent sub-samples. Sub-samples 1 and 3 were surveyed by one party of investigators and sub-samples 2 & 4 by another party of investigators. The first stage units for yield survey were a sub-sample of the villages chosen for the land utilisation survey.

2. Within a state, contiguous tehsils or parts of contiguous tehsils fairly homogeneous with respect to population density and crop-pattern were grouped together to form compact strata as far as possible such that the sum of the sizes of the villages in each stratum was exactly equal, the size of a village being the ratio of its population to the average population of a village in the population class 0-499 in the state rounded off to an integer. In the whole of India 353 strata were formed.

3. The allocation of the total sample size to the various states was done on a joint consideration of the rural population, area under cereal crops and the investigator strength. The allocation was modified to ensure a minimum sample size of 360 villages in each state and about 200 sample villages in each of the Union Territories, Manipur and Tripura. The allocation was rounded off to 24 or multiple of 24 to facilitate having 4 sub-samples of 6 villages each per stratum.

4. The frame used for selection of villages was the list of villages as per the 1961 census. Within each stratum the tehsils were arranged in a serpentine order and four independent interpenetrating sub-samples of 12 villages each were selected circularly systematically with probability proportional to size. In each sub-sample of a stratum the 6 villages with odd orders of selection formed the central sample and the remaining 6 villages formed the State sample.

5. The land utilisation survey was conducted in all the 6 villages in each of the four sub-samples for autumn, winter, spring and summer seasons. The crop-cutting experiments were conducted in villages 1, 3 and 6 of sub-samples 1 and 2 only of each stratum in each of the four seasons.

6. In sample villages meant only for land utilisation survey a circular systematic sample of 4 clusters of 5 plots each were selected per village while in sample villages meant for both land utilisation survey and crop-cutting experiments a circular systematic sample of 6 clusters of 10 plots each were selected. This selection procedure was adopted where cadastral maps for the villages were available and also in case of villages without maps where a list of plots was available. The sample clusters were formed through basic plots (equal to the number of clusters), selected circularly systematically with equal probability. If the number of plots in a village was less than 20 (for a village where only land utilisation survey was to be conducted) or less than 60 (for a village where yield survey also to be conducted) then all the plots in the village were completely enumerated. If neither the cadastral map nor the list of plots was available, a circular systematic sample of 4 or 6 households (depending on whether the village was meant to be surveyed only for land utilisation survey or both land utilisation survey and crop-cutting experiments) was selected and all the plots possessed by the selected households and situated within a radius of 5 miles from the sample village were surveyed. If the number of households in the village was less than 4 (or 6, as the case may be) all the households were taken up for the survey. The same set of sample clusters or plots possessed by the households were surveyed for each of the four seasons.

7. In each season six sub-plots were selected circularly systematically from all the sub-plots in the sample plots surveyed for land utilisation with probability proportional to the gross area under the specified crops. From the selected sub-plots, yield data were collected from circular cuts located at random in the sub-plot. For crops paddy, ragi, wheat (grown pure) or barley (grown pure) one cut was taken from a sub-plot while two cuts were taken in sub-plots growing jowar, bajra, wheat (mixed), maize or barley (mixed). Selection of sub-plots for crop-cutting experiments was done afresh for each season. If in a village the number of sub-plots having the specified crops was less than 6, all those sub-plots were taken up for crop-cutting experiments.

#### 8. Estimation procedure :

##### 8.1 Notation :

s=subscript for sth stratum/sub-stratum.

i=subscript for ith sample village/selected part of village.

k=number of strata/sub-strata in the state.

v=number of sample villages selected in the stratum and the sub-sample for the season.

Z=sum of sizes (used for selection) of the villages per stratum.

z=size (used for selection) of the village

r=adjustment ratio for revenue village selection and selection of part of the village .†

N=highest survey number (adjusted)††/highest sampling serial number of plots (adjusted).††

\*A plot is defined as distinct patch of land having a major survey number.

\*\*A sub-plot is defined as a contiguous patch of land within a plot having a particular type of utilisation. A plot may consist of one or more sub-plots.

†r= 1 When the surveyed revenue villages coincides with the sampled census village and the whole of it was surveyed.

r= The number of areal divisions/hamlet groups formed in the village if an areal division or hamlet group was selected for survey.

r= The number of revenue villages which are wholly contained in the sampled census village in case the surveyed revenue village was selected from among them.

r= 1/number of census villages wholly contained in the surveyed revenue village, when the sampled census village was one of them.

†† For selection of sample plots, the highest survey number or sampling serial number was rounded off to the next higher multiple of the cluster size (in case it was not a multiple of the cluster size).

H=total number of households in the village.

n=number of clusters/households selected.

c=cluster size (in terms of number of plots).

a=area under a particular crop.

y=yield rate for a particular crop.

8.2 The estimates of area and yield rate for each crop were obtained separately for each crop season and for each sub-sample and separately for crop grown 'pure' and 'mixed' separately. The estimate of production of a crop was obtained as a product of the estimate of the area under the crop(based on all sample villages where land utilisation survey was conducted including crop-cutting villages) and the estimate of yield rate(obtained from all sample villages where crop-cutting experiments were conducted).

#### 8.3 Acreage estimate

An estimate of the gross area under a particular crop separately for crop grown 'pure' and 'mixed' in a particular season for a given sub-sample in a state is given by

$$\hat{A} = \sum_{s=1}^k Z \sum_{i=1}^v \frac{r_{si}}{z_{si}} \frac{N's_i}{n_{si}}$$

where Z is constant for all strata and v=6 and

$$\begin{aligned} N's_i &= N_{si} / C_{si} && \text{if clusters of plots were selected using map or a list of plots} \\ &= H_{si} && \text{if households were selected} \\ \frac{N's_i}{n_{si}} &= 1 && \text{for a village where all the plots or households in the village were surveyed} \\ a_{si} &= && \text{gross area in all the sampled clusters plots/possessed by the sampled households of the village} \\ \hat{A}_s &= \sum_{s=1}^k \hat{A}_s && \text{where } \hat{A}_s \text{ is the } s\text{th stratum estimate} \\ \hat{A}_s &= \frac{Z}{v} \sum_{i=1}^v \frac{A_{si}}{z_{si}} && \text{and } \hat{A}_s \text{ is the estimate for } i\text{th village in the } s\text{th stratum} = r_{si} \frac{N's_i}{n_{si}} a_{si} \end{aligned}$$

#### 8.4 Substitution

If any of the selected village was a casualty for the land utilisation survey for a season in the sense that it could not be surveyed, it was substituted by the next sample village selected for land utilisation survey in that stratum. Similarly if a cluster/household selected for acreage survey in a village was a casualty it was substituted by the next surveyed cluster household. Likewise if a selected plot in a cluster selected for acreage survey was a casualty, it was substituted by the next plot.

#### 8.5 Production estimate

The production estimate P of a crop (obtained separately for pure and mixed crop) is the product of Y, and estimate of the yield rate of the crop (pure or mixed as the case may be) based on the villages reporting crop-cutting experiments and A, an estimate of the area under the crop (area under pure crop or gross area under mixed crop as the case may be) based on all the villages selected for the land utilisation survey.

#### 8.6 The estimate Y is given by

$$\hat{Y} = \Sigma' \hat{A}_s \hat{y}_s / \Sigma' \hat{A}_s$$

where  $\hat{y}_s$ =simple average of yield rates over the cuts taken for the crop in the  $s$ th stratum.

$\hat{A}_s$ =obtained as described in paragraph 8.3

$\Sigma'$  denotes summation over only these strata reporting crop-cutting experiments for that crop.

8.7 As mentioned earlier, the area survey was planned to be conducted in all the sample villages of each of the four sub-samples while crop-cutting experiments were planned for a sub-set of villages of sub-samples 1 and 2 only. The production estimates have therefore been obtained :

(i) as the product of acreage estimate from sub-samples 1 and 3 combined and the estimates of yield rate from sub-sample 1.

(ii) as the product of acreage estimate from sub-sample 2 and 4 combined and the estimate of yield rate from sub-sample 2.

(i) gives the estimates based on one half of the sample surveyed by one party of investigation (designated as half-sample 1) and

(ii) gives estimates based on the other half of the sample, surveyed by another party (designated as half-sample 2).

The combined production estimate based on both the half-samples was obtained as the mean of the two half-sample estimates.

8.8 The 'total' estimates of production of a crop is given by the sum of the production estimates for the grown 'pure' and 'mixed'.

8.9 The estimates given above are for the green weight of the crop. The estimate of production of dry crop is obtained by multiplying the green weight of crop by a drage factor applied at the State level. This factor is obtained as the ratio of the total dry weight to the total green weight of that crop (pure and mixed taken together) obtained from the cuts of 2' 3" radius. The drage factors are obtained separately for each sub-sample and for each season.

8.10 The estimates of area and production of crops for the whole agricultural year is given as the sum of the estimates for the four seasons autumn, winter, spring and summer.
